1 Data Structures

1.1 Disjoin Set Union

```
struct DSU {
    vector<int> par;
    vector<int> sz;

    DSU(int n) {
        FOR(i, 0, n) {
            par.pb(i);
            sz.pb(1);
        }
    }

    int find(int a) {
        return par[a] = par[a] == a ? a : find(par[a]);
    }

    bool same(int a, int b) {
        return find(a) == find(b);
    }

    void unite(int a, int b) {
        a = find(a);
        b = find(b);
        if(sz[a] > sz[b]) swap(a, b);
        sz[b] += sz[a];
        par[a] = b;
    }
};
```

1.2 Fenwick 2D

```
struct Fenwick2D {
    vector<vector<ll>>> bit;
    int n, m;
    Fenwick2D(int _n, int _m) {
        n = _n; m = _m;
        bit = vector<vector<ll>>>(n+1, vector<ll>(m+1, 0));
    }
    ll sum(int x, int y) {
        ll ret = 0;
        for (int i = x; i > 0; i -= i & (-i))
            for (int j = y; j > 0; j -= j & (-j))
                ret += bit[i][j];
        return ret;
    }
};
```

```
    }
    ll sum(int x1, int y1, int x2, int y2) {
        return sum(x2, y2) - sum(x2, y1-1) - sum(x1-1, y2) + sum(x1-1, y1-1);
    }
    void add(int x, int y, ll delta) {
        for (int i = x; i <= n; i += i & (-i))
            for (int j = y; j <= m; j += j & (-j))
                bit[i][j] += delta;
    }
};
```

1.3 Fenwick Tree Point Update And Range Query

```
struct Fenwick {
    vector<ll> tree;
    int n;
    Fenwick(){}
    Fenwick(int _n) {
        n = _n;
        tree = vector<ll>(n+1, 0);
    }
    void add(int i, ll val) { // arr[i] += val
        for(; i <= n; i += i & (-i)) tree[i] += val;
    }
    ll get(int i) { // arr[i]
        return sum(i, i);
    }
    ll sum(int i) { // arr[1]+...+arr[i]
        ll ans = 0;
        for(; i > 0; i -= i & (-i)) ans += tree[i];
        return ans;
    }
    ll sum(int l, int r) { // arr[l]+...+arr[r]
        return sum(r) - sum(l-1);
    }
};
```

1.4 Fenwick Tree Range Update And Point Query

```
struct Fenwick {
    vector<ll> tree;
    vector<ll> arr;
    int n;
    Fenwick(vector<ll> _arr) {
        n = _arr.size();
        arr = _arr;
        tree = vector<ll>(n+2, 0);
    }
};
```

```

    }
    void add(int i, ll val) { // arr[i] += val
        for(; i <= n; i += i&(-i)) tree[i] += val;
    }
    void add(int l, int r, ll val) { // arr[l..r] += val
        add(l, val);
        add(r+1, -val);
    }
    ll get(int i) { // arr[i]
        ll sum = arr[i-1]; // zero based
        for(; i > 0; i -= i&(-i)) sum += tree[i];
        return sum; // zero based
    }
};

```

1.5 Fenwick Tree Range Update And Range Query

```

struct RangedFenwick {
    Fenwick F1, F2; // support range query and point update
    RangedFenwick(int _n) {
        F1 = Fenwick(_n+1);
        F2 = Fenwick(_n+1);
    }
    void add(int l, int r, ll v) { // arr[l..r] += v
        F1.add(l, v);
        F1.add(r+1, -v);
        F2.add(l, v*(l-1));
        F2.add(r+1, -v*r);
    }
    ll sum(int i) { // arr[1..i]
        return F1.sum(i)*i-F2.sum(i);
    }
    ll sum(int l, int r) { // arr[l..r]
        return sum(r)-sum(l-1);
    }
};

```

1.6 Implicit Treap

```

template <typename T>
struct Node {

        return in >> v.x >> v.y;
    }
    T norm() { // squared length
        return (*this)*(*this);
    }
    ld len() {
        return sqrt(norm());
    }
    ld angle(const Vec& other) { // angle between this and other vector
        return acosl((*this)*other/len()/other.len());
    }
    Vec perp() {
        return Vec(-y, x);
    }
};
/* Cross product of 3d vectors: (ay*bz-az*by, az*bx-ax*bz, ax*by-ay*bx)
*/
```

3.2 Circle Circle Intersection

Let's say that the first circle is centered at $(0,0)$ (if it's not, we can move the origin to the center of the first circle and adjust the coordinates), and the second one is at (x_2, y_2) . Then, let's construct a line $Ax + By + C = 0$, where $A = -2x_2, B = -2y_2, C = x_2^2 + y_2^2 + r_1^2 - r_2^2$. Finding the intersection between this line and the first circle will give us the answer. The only tricky case: if both circles are centered at the same point. We handle this case separately.

3.3 Circle Line Intersection

```
double r, a, b, c; // ax+by+c=0, radius is at (0, 0)
// If the center is not at (0, 0), fix the constant c to translate everything so that center
// is at (0, 0)
double x0 = -a*c/(a*a+b*b), y0 = -b*c/(a*a+b*b);
if (c*c > r*r*(a*a+b*b)+eps)
    puts ("no points");
else if (abs (c*c - r*r*(a*a+b*b)) < eps) {
    puts ("1 point");
    cout << x0 << ' ' << y0 << '\n';
}
```

```

}
else {
    double d = r*r - c*c/(a*a+b*b);
    double mult = sqrt (d / (a*a+b*b));
    double ax, ay, bx, by;
    ax = x0 + b * mult;
    bx = x0 - b * mult;
    ay = y0 - a * mult;
    by = y0 + a * mult;
    puts ("2 points");
    cout << ax << ' ' << ay << '\n' << bx << ' ' << by << '\n';
}

```

3.4 Common Tangents To Two Circles

```

struct pt {
    double x, y;

    pt operator- (pt p) {
        pt res = { x-p.x, y-p.y };
        return res;
    }
};

struct circle : pt {
    double r;
};

struct line {
    double a, b, c;
};

void tangents (pt c, double r1, double r2, vector<line> & ans) {
    double r = r2 - r1;
    double z = sqrt(c.x) + sqrt(c.y);
    double d = z - sqrt(r);
    if (d < -eps) return;
    d = sqrt (abs (d));
    line l;
    l.a = (c.x * r + c.y * d) / z;
    l.b = (c.y * r - c.x * d) / z;
    l.c = r1;
    ans.push_back (l);
}

vector<line> tangents (circle a, circle b) {
    vector<line> ans;
    for (int i=-1; i<=1; i+=2)
        for (int j=-1; j<=1; j+=2)
            tangents (b-a, a.r*i, b.r*j, ans);
    for (size_t i=0; i<ans.size(); ++i)
        ans[i].c -= ans[i].a * a.x + ans[i].b * a.y;
    return ans;
}

```

```

}

```

3.5 Convex Hull Gift Wrapping

```

vector<Vec<int>> buildConvexHull(vector<Vec<int>>& pts) {
    int n = pts.size();
    sort(pts.begin(), pts.end());
    auto currP = pts[0]; // choose some extreme point to be on the hull

    vector<Vec<int>> hull;
    set<Vec<int>> used;
    hull.pb(pts[0]);
    used.insert(pts[0]);
    while(true) {
        auto candidate = pts[0]; // choose some point to be a candidate

        auto currDir = candidate-currP;

}
```

3.7 Line

```
template <typename T>
struct Line { // expressed as two vectors
    Vec<T> start, dir;
    Line() {}
    Line(Vec<T> a, Vec<T> b): start(a), dir(b-a) {}
}
```

```
Vec<ld> intersect(Line l) {
    ld t = ld((l.start-start)^(l.dir)/(dir^l.dir);
    // For segment-segment intersection this should be in range [0, 1]
    Vec<ld> res(start.x, start.y);
    Vec<ld> dirld(dir.x, dir.y);
    return res + dirld*t;
}
};
```

3.8 Number Of Lattice Points On Segment

Let's say we have a line segment from (x_1, y_1) to (x_2, y_2) . Then, the number of lattice points on this segment is given by

$$\gcd(x_2 - x_1, y_2 - y_1) + 1.$$

3.9 Pick's Theorem

We are given a lattice polygon with non-zero area. Let's denote its area by S , the number of points with integer coordinates lying strictly inside the polygon by I and the number of points lying on the sides of the polygon by B . Then:

$$S = I + \frac{B}{2} - 1.$$

4 Graphs

4.1 Bellman Ford Algorithm

```
struct Edge
{
    int a, b, cost;
};

int n, m, v; // v - starting vertex
vector<Edge> e;
```

    if (timestamp[e.from] == cur_time && timestamp[e.to] != cur_time) {
        cc.insert(e.idx);
    }
}
// (# of edges in min-cut, capacity of cut)
// [indices of edges forming the cut]
cout << cc.size() << " " << f << endl;
for (auto x : cc) cout << x + 1 << " ";

```

4.11 Number Of Paths Of Fixed Length

Let G be the adjacency matrix of a graph. Then $C_k = G^k$ gives a matrix, in which the value $C_k[i][j]$ gives the number of paths between i and j of length k .

4.12 Shortest Paths Of A Fixed Length

Define $A \odot B = C \iff C_{ij} = \min_{p=1..n} (A_{ip} + B_{pj})$. Let G be the adjacency matrix of a graph. Also, let $L_k = G \odot \dots \odot G = G^{\odot k}$. Then the value $L_k[i][j]$ denotes the length of the shortest path between i and j which consists of exactly k edges.

4.13 Strongly Connected Components

```

return ss.str();
}

```

5.2 Burnside's Lemma

Let G be a finite group that acts on a set X . For each g in G let X^g denote the set of elements in X that are fixed by g . Burnside's lemma asserts the following formula for the number of orbits:

$$|X/G| = \frac{1}{|G|} \sum_{g \in G} |X^g|.$$

Example. Coloring a cube with three colors.

Let X be the set of 3^6 possible face color combinations. Let's count the sizes of the fixed sets for each of the 24 rotations:

- one 0-degree rotation which leaves all 3^6 elements of X unchanged
- six 90-degree face rotations, each of which leaves 3^3 elements of X unchanged
- three 180-degree face rotation, each of which leaves 3^4 elements of X unchanged

- eight 120-degree vertex rotations, each of which leaves 3^2 elements of X unchanged
- six 180-degree edge rotations, each of which leaves 3^3 elements of X unchanged

The average is then $\frac{1}{24}(3^6 + 6 \cdot 3^3 + 3 \cdot 3^4 + 8 \cdot 3^2 + 6 \cdot 3^3) = 57$. For n colors: $\frac{1}{24}(n^6 + 3n^4 + 12n^3 + 8n^2)$.

Example. Coloring a circular stripe of n cells with two colors.

X is the set of all colored striped (it has 2^n elements), G is the group of rotations (n elements - by 0 cells, by 1 cell, ..., by $(n-1)$ cells). Let's fix some K and find the number of stripes that are fixed by the rotation by K cells. If a stripe becomes itself after rotation by K cells, then its 1st cell must have the same color as its $(1+K \bmod n)$ -th cell, which is in turn the same as its $(1+2K \bmod n)$ -th cell, etc., until $mK \bmod n = 0$. This will happen when $m = n/\gcd(K, n)$. Therefore, we have $n/\gcd(K, n)$ cells that must all be of the same color. The same will happen when starting from the second cell and so on. Therefore, all cells are separated into $\gcd(K, n)$ groups, with each group being of one color, and that yields $2^{\gcd(K, n)}$ choices. That's why the answer to the original problem is $\frac{1}{n} \sum_{k=0}^{n-1} 2^{\gcd(k, n)}$.

5.3 Chinese Remainder Theorem

Let's say we have some numbers m_i , which are all mutually coprime. Also, let $M = \prod_i m_i$. Then the system of congruences

$$\begin{cases} x \equiv a_1 \pmod{m_1} \\ x \equiv a_2 \pmod{m_2} \\ \dots \\ x \equiv a_k \pmod{m_k} \end{cases}$$

is equivalent to $x \equiv A \pmod{M}$ and there exists a unique number A satisfying $0 \leq A \leq M$.

Solution for two: $x \equiv a_1 \pmod{m_1}, x \equiv a_2 \pmod{m_2}$. Let $x = a_1 + km_1$. Substituting into the second congruence: $km_1 \equiv a_2 - a_1$

$(\text{mod } m_2)$. Then, $k = (m_1)_{m_2}^{-1}(a_2 - a_1) \pmod{m_2}$. and we can easily find x . This can be extended to multiple equations by solving them one-by-one.

If the moduli are not coprime, solve the system $y \equiv 0 \pmod{\frac{m_1}{g}}, y \equiv \frac{a_2 - a_1}{g} \pmod{\frac{m_2}{g}}$ for y . Then let $x \equiv gy + a_1 \pmod{\frac{m_1 m_2}{g}}$.

5.4 Euler Totient Function

```
// Number of numbers x < n so that gcd(x, n) = 1
ll phi(ll n) {
    if(n == 1) return 1;
    auto f = factorize(n);
    ll res = n;
    for(auto p : f) {
        res = res - res/p.first;
    }
    return res;
}
```

5.5 Extended Euclidean Algorithm

```
// ax+by=gcd(a,b)
void solveEq(ll a, ll b, ll& x, ll& y, ll& g) {
    if(b==0) {
        x = 1;
        y = 0;
        g = a;
        return;
    }
    ll xx, yy;
    solveEq(b, a%b, xx, yy, g);
    x = yy;
    y = xx-yy*(a/b);
}
// ax+by=c
bool solveEq(ll a, ll b, ll c, ll& x, ll& y, ll& g) {
    solveEq(a, b, x, y, g);
    if(c%g != 0) return false;
    x *= c/g; y *= c/g;
    return true;
}
// Finds a solution (x, y) so that x >= 0 and x is minimal
```

```
bool solveEqNonNegX(ll a, ll b, ll c, ll& x, ll& y, ll& g) {
    if(!solveEq(a, b, c, x, y, g)) return false;
    ll k = x*g/b;
    x = x - k*b/g;
    y = y + k*a/g;
    if(x < 0) {
        x += b/g;
        y -= a/g;
    }
    return true;
}
```

All other solutions can be found like this:

$$x' = x - k\frac{b}{g}, y' = y + k\frac{a}{g}, k \in \mathbb{Z}$$

5.6 Factorization With Sieve

```
// Use linear sieve to calculate minDiv
vector<pll> factorize(ll x) {
    vector<pll> res;
    ll prev = -1;
    ll cnt = 0;
    while(x != 1) {
        ll d = minDiv[x];
        if(d == prev) {
            cnt++;
        } else {
            if(prev != -1) res.pb({prev, cnt});
            prev = d;
            cnt = 1;
        }
        x /= d;
    }
    res.pb({prev, cnt});
    return res;
}
```

5.7 FFT With Modulo

```

}

/* Usage:
* addString(strs[i], i);
* auto matches = walk(text);
* .. do what you need with the matches - count, check if some id exists, etc ..
* Some applications:
* - Find all matches: just use the walk function
* - Find lexicographically smallest string of a given length that doesn't match any of
  the given strings:
* For each node, check if it produces any matches (it either contains some marks or
  walkUp(v) returns some marks).
* Remove all nodes which produce at least one match. Do DFS in the remaining
  graph, since none of the remaining nodes
* will ever produce a match and so they're safe.
* - Find shortest string containing all given strings:
* For each vertex store a mask that denotes the strings which match at this state.
  Start at (v = root, mask = 0),
* we need to reach a state (v, mask=2^n-1), where n is the number of strings in the
  set. Use BFS to transition between states
* and update the mask.
*/
