```

3.12 Number Of Paths Of Fixed Length

Let G be the adjacency matrix of a graph. Then $C_k = G^k$ gives a matrix, in which the value $C_k[i][j]$ gives the number of paths between i and j of length k.

3.13 Shortest Paths Of Fixed Length

Define $A \odot B = C \iff C_{ij} = \min_{p=1..n} (A_{ip} + B_{pj})$. Let G be the adjacency matrix of a graph. Also, let $L_k = G \odot ... \odot G = G^{\odot k}$. Then the value $L_k[i][j]$ denotes the length of the shortest path between i and j which consists of exactly k edges.

        }
    if(used.find(candidate) != used.end()) break;
    hull.pb(candidate);
    used.insert(candidate);
    currP = candidate;
return hull;
```

4.4 Convex Hull With Graham's Scan

```
Takes in >= 3 points
// Returns convex hull in clockwise order
^{'}// Ignores points on the border
vector<Vec<int>> buildConvexHull(vector<Vec<int>> pts)
   if(pts.size() <= 3) return pts;
   sort(pts.begin(), pts.end());
stack<Vec<int>> hull;
   hull.push(pts[0]);
   auto p = pts[0];
   sort(pts.begin()+1, pts.end(), [&](Vec<int> a, Vec<int>
         b) -> bool {
        // p->a->b is a ccw turn
       int turn = sgn((a-p)^(b-a));

//if(turn == 0) return (a-p).norm() > (b-p).norm();
       // ^ among collinear points, take the farthest one
       return turn == 1;
   hull.push(pts[1]);
   FOR(i, 2, (int)pts.size()) {
       auto c = pts[i];
       if(c == hull.top()) continue;
       while(true) {
   auto a = hull.top(); hull.pop();
           auto b = hull.top();
           auto ba = a-b;
            auto ac = c-a;
           if((ba^ac) > 0) {
               hull.push(a);
               break;
           e^{if(ax)} else if((ba^ac) == 0) {
 if(ba*ac < 0) c = a;
               // ^ c is between b and a, so it shouldn't be
                      added to the hull
               break:
           }
       hull.push(c);
   vector<Vec<int>> hullPts;
   while(!hull.empty()) {
       hullPts.pb(hull.top());
       hull.pop();
   return hullPts;
```

4.5 Circle Line Intersection

```
double r, a, b, c; // ax+by+c=0, radius is at (0, 0) // If the center is not at (0, 0), fix the constant c to translate everything so that center is at (0, 0) double x0 = -a*c/(a*a+b*b), y0 = -b*c/(a*a+b*b); if (c*c > r*r*(a*a+b*b)+eps) puts ("noupoints"); else if (abs (c*c - r*r*(a*a+b*b)) < eps) { puts ("1upoint"); cout << x0 << 'u' << y0 << '\n'; } else { double d = r*r - c*c/(a*a+b*b); double mult = sqrt (d / (a*a+b*b)); double ax, ay, bx, by; ax = x0 + b * mult; bx = x0 - b * mult; by = y0 - a * mult; by = y0 + a * mult; puts ("2upoints"); cout << ax << 'u' << ay << '\n' << bx << '\n' << by << '\n'; << by << '\n'; << by << '\n' << bx << '\n' << by << '\n'; << by << '
```

4.6 Circle Circle Intersection

Let's say that the first circle is centered at (0,0) (if it's not, we can move the origin to the center of the first circle and adjust the coordinates), and the second one is at (x_2, y_2) . Then, let's construct a line Ax + By + C = 0, where $A = -2x_2, B = -2y_2, C = x_2^2 + y_2^2 + r_1^2 - r_2^2$. Finding the intersection between this line and the first circle will give us the answer. The only tricky case: if both circles are centered at the same point. We handle this case separately.

4.7 Common Tangents To Two Circles

```
struct pt {
    double x, y;
    pt operator- (pt p) {
        pt res = \{x-p.x, y-p.y\};
struct circle : pt {
   double r;
struct line {
   double a, b, c;
void tangents (pt c, double r1, double r2, vector<line> & ans)
    double r = r2 - r1;
    double z = sqr(c.x) + sqr(c.y);
    double d = z - sqr(r);
   if (d < -eps) return;
    d = sqrt (abs (d));
   line l:
   l.a = (c.x * r + c.y * d) / z;
l.b = (c.y * r - c.x * d) / z;
    ans.push_back (l);
vector<line> tangents (circle a, circle b) {
    vector<line> ans;
    for (int i=-1; i<=1; i+=2)
        for (int j=-1; j<=1; j+=2)
           tangents (b-a, a.r*i, b.r*j, ans);
```

```
 \begin{array}{l} {\rm for\ (size\_t\ i=0;\ i<ans.size();\ ++i)}\\ {\rm ans[i].c\ -=\ ans[i].a\ *\ a.x\ +\ ans[i].b\ *\ a.y;}\\ {\rm return\ ans;} \end{array}
```

4.8 Number Of Lattice Points On Segment

Let's say we have a line segment from (x_1, y_1) to (x_2, y_2) . Then, the number of lattice points on this segment is given by

$$gcd(x_2-x_1,y_2-y_1)+1.$$

4.9 Pick's Theorem

We are given a lattice polygon with non-zero area. Let's denote its area by S, the number of points with integer coordinates lying strictly inside the polygon by I and the number of points lying on the sides of the polygon by B. Then:

$$S = I + \frac{B}{2} - 1.$$

5 Math

5.1 Linear Sieve

```
 \begin{split} & ll \; minDiv[MAXN+1]; \\ & vector < ll > \; primes; \\ & void \; sieve(ll \; n) \{ \\ & \; FOR(k,\; 2,\; n+1) \{ \\ & \; minDiv[k] = k; \\ \} \\ & \; FOR(k,\; 2,\; n+1) \; \{ \\ & \; if(minDiv[k] == k) \; \{ \\ & \; primes.pb(k); \\ \} \\ & \; for(auto \; p: primes) \; \{ \\ & \; if(p > minDiv[k]) \; break; \\ & \; if(p * k > n) \; break; \\ & \; minDiv[p * k] = p; \\ \} \\ \} \\ \} \end{aligned}
```

5.2 Extended Euclidean Algorithm

```
// ax+by=gcd(a,b)
void solveEq(ll a, ll b, ll& x, ll& y, ll& g) {
    if(b==0) {
        x = 1;
        y = 0;
        g = a;
        return;
    }
    ll xx, yy;
    solveEq(b, a%b, xx, yy, g);
    x = yy;
    y = xx-yy*(a/b);
}
```

```
 \begin{tabular}{ll} // & ax+by=c \\ & bool & solveEq(a, b, x, y, g); \\ & solveEq(a, b, x, y, g); \\ & if(c\%g != 0) & return false; \\ & x *= c/g; y *= c/g; \\ & return true; \\ \end{tabular}   \begin{tabular}{ll} // & Finds a solution (x, y) so that x >= 0 and x is minimal bool & solveEqNonNegX(ll a, ll b, ll c, ll& x, ll & y, ll& g) { if(!solveEq(a, b, c, x, y, g)) & return false; ll k = x*g/b; \\ & x = x - k*b/g; \\ & y = y + k*a/g; \\ & if(x < 0) & \{ \\ & x += b/g; \\ & y -= a/g; \\ & \} \\ & return true; \\ \end{tabular}
```

All other solutions can be found like this:

$$x' = x - k \frac{b}{g}, y' = y + k \frac{a}{g}, k \in \mathbb{Z}$$

5.3 Chinese Remainder Theorem

Let's say we have some numbers m_i , which are all mutually coprime. Also, let $M = \prod_i m_i$. Then the system of congruences

$$\begin{cases} x \equiv a_1 \pmod{m_1} \\ x \equiv a_2 \pmod{m_2} \\ \dots \\ x \equiv a_k \pmod{m_k} \end{cases}$$

is equivalent to $x \equiv A \pmod{M}$ and there exists a unique number A satisfying $0 \le A \le M$.

Solution for two: $x \equiv a_1 \pmod{m_1}$, $x \equiv a_2 \pmod{m_2}$. Let $x = a_1 + km_1$. Substituting into the second congruence: $km_1 \equiv a_2 - a_1 \pmod{m_2}$. Then, $k = (m_1)_{m_2}^{-1}(a_2 - a_1) \pmod{m_2}$. and we can easily find x. This can be extended to multiple equations by solving them one-by-one.

If the moduli are not coprime, solve the system $y \equiv 0 \pmod{\frac{m_1}{g}}, y \equiv \frac{a_2 - a_1}{g} \pmod{\frac{m_2}{g}}$ for y. Then let $x \equiv gy + a_1 \pmod{\frac{m_1 m_2}{g}}$.

5.4 Euler Totient Function

5.5 Factorization With Sieve

```
// Use linear sieve to calculate minDiv
vector<pll> factorize(ll x) {
    vector<pll> res;
    ll prev = -1;
    ll cnt = 0;
    while(x != 1) {
        ll d = minDiv[x];
        if(d == prev) {
            cnt++;
        } else {
            if(prev != -1) res.pb({prev, cnt});
            prev = d;
            cnt = 1;
        }
        x /= d;
    }
    res.pb({prev, cnt});
    return res;
}
```

5.6 Modular Inverse

5.7 Simpson Integration

5.8 Burnside's Lemma

Let G be a finite group that acts on a set X. For each g in G let X^g denote the set of elements in X that are fixed by g. Burnside's lemma asserts the following formula for the number of orbits:

$$|X/G| = \frac{1}{|G|} \sum_{g \in G} |X^g|.$$

Example. Coloring a cube with three colors.

Let X be the set of 3^6 possible face color combinations. Let's count the sizes of the fixed sets for each of the 24 rotations:

• one 0-degree rotation which leaves all 3^6 elements of X unchanged

- six 90-degree face rotations, each of which leaves 3^3 elements of X unchanged
- three 180-degree face rotation, each of which leaves 3^4 elements of X unchanged
- eight 120-degree vertex rotations, each of which leaves 3^2 elements of X unchanged
- six 180-degree edge rotations, each of which leaves 3^3 elements of X unchanged

The average is then $\frac{1}{24}(3^6 + 6 \cdot 3^3 + 3 \cdot 3^4 + 8 \cdot 3^2 + 6 \cdot 3^3) = 57$. For n colors: $\frac{1}{24}(n^6 + 3n^4 + 12n^3 + 8n^2)$.

Example. Coloring a circular stripe of n cells with two colors.

X is the set of all colored striped (it has 2^n elements), G is the group of rotations (n elements by 0 cells, by 1 cell, ..., by (n-1) cells). Let's fix some K and find the number of stripes that are fixed by the rotation by K cells. If a stripe becomes itself after rotation by K cells, then its 1st cell must have the same color as its $(1+K \mod n)$ th cell, which is in turn the same as its (1 + 2K) $\mod n$)-th cell, etc., until $mK \mod n = 0$. This will happen when m = n/gcd(K, n). Therefore, we have n/qcd(K, n) cells that must all be of the same color. The same will happen when starting from the second cell and so on. Therefore, all cells are separated into gcd(K, n) groups, with each group being of one color, and that yields $2^{gcd(K,n)}$ choices. That's why the answer to the original problem is $\frac{1}{n} \sum_{k=0}^{n-1} 2^{\gcd(k,n)}$.

5.9 FFT

```
namespace FFT {
   int n:
   vector<int> r:
   vector<complex<ld>> omega;
   int logN, pwrN;
   void initLogN() {
       logN = 0;
       pwrN = 1;
       while (pwrN < n) {
           pwrN *= 2;
           logN++;
       n = pwrN;
   }
   void initOmega() {
       FOR(i, 0, pwrN) {
           omega[i] = { \cos(2 * i*PI / n), \sin(2 * i*PI / n) };
   }
   void initR() {
       FOR(i, 1, pwrN) {

r[i] = r[i / 2] / 2 + ((i \& 1) << (logN - 1));
   }
   void initArrays() {
```

```
r.resize(pwrN);
    omega.clear();
    omega.resize(pwrN);
void init(int n) {
    FFT::n = n;
    initLogN();
    initArrays()
    initOmega();
   initR();
void fft(complex<ld> a[], complex<ld> f[]) {
    FOR(i, 0, pwrN) {
        f[i] = a[r[i]];
    for (ll k = 1; k < pwrN; k *= 2) {
        for (ll i = 0; i < pwrN; i += 2 * k) {
            for (ll j = 0; j < k; j++) {
    auto z = omega[j*n / (2 * k)] * f[i + j + k];
    f[i + j + k] = f[i + j] - z;
                 f[i\,+\,j]\,+=\,z;
       }
```

5.10 FFT With Modulo

```
bool is
Generator(ll g) {
    if (pwr(g, M - 1) != 1) return false;
for (ll i = 2; i*i <= M - 1; i++) {
       if ((M - 1) % i == 0) {
            ll q = i;
            if (isPrime(q)) {

    walkUp(getExitLink(v), matches);
}
   returns the IDs of matched strings.
   Will contain duplicates if multiple matches of the same
      string are found.
vector<int> walk(const string& s) {
    vector < int > matches;
   int curr = 0:
   for(char c : s) {
        curr = go(curr, c);
        if(!t[curr].marks.empty()) {
           for(auto m: t[curr].marks) matches.pb(m);
        walkUp(getExitLink(curr), matches);
   return matches:
}
/* Usage:
 * addString(strs[i], i);
* auto matches = walk(text);
   .. do what you need with the matches - count, check if some id exists, etc ..
 * Some applications:
 * - Find all matches: just use the walk function
 \ast - Find lexicographically smallest string of a given length
       that doesn't match any of the given strings:
 * For each node, check if it produces any matches (it either
       contains some marks or walkUp(v) returns some marks)
 * Remove all nodes which produce at least one match. Do
       DFS in the remaining graph, since none of the
       remaining nodes
 * will ever produce a match and so they're safe.
   - Find shortest string containing all given strings:
 * For each vertex store a mask that denotes the strings which
 match at this state. Start at (v = root, mask = 0), * we need to reach a state (v, mask=2^n-1), where n is the
       number of strings in the set. Use BFS to transition
       between states
  and update the mask.
```
